Abstract. Metastasis-associated in colon cancer-1 (MACC1) is a newly identified gene that is involved in the development and progression of hepatocellular carcinoma (HCC), however its investigation has not been comprehensive. In the present study, in vitro techniques, including immunohistochemistry, western blotting, reverse transcription quantitative polymerase chain reaction, metabolic assay, MTT assay, colony formation assay and prognostic analysis were used to confirm the involvement of MACC1 in HCC. Histological examination confirmed that the protein expression of MACC1 was upregulated in HCC and was associated with the hexokinase-2 (HK2) protein, which also indicates a poor prognosis. Knockdown of MACC1 induced the reduction of glycogen consumption and lactate production, which then lead to a marked reduction of proliferation in the MHCC‑97H cells. However, the overexpression of MACC1 produced the opposite results in the HepG2 cells. These results suggested that MACC1 leads to a poor prognosis in HCC, partly by promoting proliferation via enhancement in glucose metabolism by HK2. Therefore, this pathway has the potential to become an important therapeutic target in HCC.

Introduction

Hepatocellular carcinoma (HCC) is the fifth most common type of cancer and has the third highest rate of tumor-associated mortality worldwide (1). Surgical resection is one of the most effective treatment options for patients with HCC (2). However, the majority of patients are unable to undergo curative resection due to the advanced cancer staging when first diagnosed. This is considered to be associated with the distinctive rapid progression observed in HCC. Therefore, there is an urgent requirement to understand the mechanism underlying the rapid progression of HCC.

Metastasis-associated in colon cancer-1 (MACC1) is a novel oncogenic factor involved in tumor growth and metastasis, and is aberrantly overexpressed in various types of tumor, including lung cancer (3), gastric cancer (4), colorectal cancer (5,6) and breast cancer (7). Our preliminary investigation revealed that MACC1 was aberrantly upregulated in HCC tissues compared with adjacent liver tissues, and in vitro experiments revealed that the overexpression of MACC1 promoted the migration and invasive ability of HCC cells, potentially via upregulating matrix metalloproteinase (MMP)2 and MMP9 (8). Another study demonstrated that overexpression of MACC1 induces the increasing expression of downstream factors, including hepatocyte growth factor (HGF) and C‑met, and promotes tumor growth and metastasis in colorectal cancer (9,10). However, the molecular mechanism whereby MACC1 leads to HCC progression remains to be elucidated.

In the 1930s, Warburg et al described the phenomenon that glycolysis was increased despite a adequate supply of oxygen, which is now well-known as the Warburg effect in cancer cells (11). Hexokinase-2 (HK2), identified as a key rate-limiting enzyme in glucose metabolism, catalyzes the reaction of the first step of glycolysis and has an irreplaceable role in cancer glucose metabolism (12). Furthermore, with the unlimited proliferation of tumor cells, the demand for energy and the expression of basic glycolytic enzymes, particularly HK2, increases markedly in the majority of tumors (13,14). In addition, the overexpression of HK2 enhances the affinity of tumor cells for adenosine triphosphate (ATP), promotes tumor cells to uptake ATP and, in turn, improves the level of energy production in cancer cells. Therefore, the HK2 expression level in tumor cells may be a potential marker for prognosis in HCC patients.

of oxidative phosphorylation in an environment of low ATP (15).

The MACC1-HGF/C-met pathway is important in cellular growth, epithelial-mesenchymal transition, angiogenesis, cell motility, invasiveness and metastasis through the activation of the mitogen-activated protein kinase (MAPK) and phosphoinositide 3-kinase (PI3K)-Akt signaling pathways (9,16,17). To assess the correlation between MACC1 and cancer glucose metabolism in HCC, the present study used in vitro assays to investigate the expression of HK2, an essential glycolytic enzyme and downstream factor of the PI3K/AKT signaling pathway (18,19), and analyzed the correlation between the two proteins and their role in postsurgical survival.

Materials and methods

 Patients and specimens. A total of 80 patients with HCC [Child-Pugh A to B, scored as previously described (20)] were registered in the present study between February 2006 and January 2008, including 58 males and 22 females (mean age 51 years; range 24-76), who had not received preoperative chemotherapy or embolization. Following necessary preoperative examinations, all the patients underwent liver resection. Tumor tissue and matched normal tumor-adjacent tissue specimens (≥2 cm distance to the resection margin) were collected and immediately stored in paraformaldehyde for immunohistochemical analysis or at -80°C for western blot analysis, respectively. Clinical data were obtained from the patient’s medical records.

 Written informed consent was obtained from all patients. The Xi’an Jiaotong University Ethics committee approved all procedures, according to the The Declaration of Helsinki, 1975 (21).

Cell culture and transfection. Liver cell lines (HepG2, Hep3B, SMMC-7721, Bel-7402, Huh7, MHCC-97H and LO2) were obtained from the Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences (Shanghai, China). All the cells were maintained in Dulbecco’s modified Eagle’s medium (DMEM; Hyclone, Logan, UT, USA) containing 10% fetal bovine serum (FBS; Gibco BRL, Gaithersburg, MD, USA) and 1% antibiotic-antimycotic (Gibco BRL, Gaithersburg, MD, USA) with 100 U/ml penicillin and 100 µg/ml streptomycin (Sigma-Aldrich, St. Louis, MO, USA) and cultured in a humidified 5% CO2 incubator at 37°C for 48-72 h.

 The MACC1-expressing plasmid and control plasmid (pCMV6-Entry; GenePharma, Shanghai, China) were transfected into HepG2 cells using Roche FuGENE® 6 Transfection reagent (Roche Diagnostics, Indianapolis, IN, USA), and stably expressing clones were selected by G418 at a dose of 300 µg/ml for 2 weeks. Western blot analysis confirmed the overexpression of MACC1 in the selected stably expressing clones (Fig. 5A). MACC1 small interfering (si)RNA and control siRNA were transfected into the MHCC-97H cells using the siPORT™ NeoFX™ transfection agent purchased from Applied Biosystems (Carlsbad, CA, USA).

Immunohistochemistry. Tumor samples were fixed in 10% buffered formalin solution (Shaanxi Xianfeng Biotechnology Co., Ltd, Xi’an, China) and embedded in paraffin (Shaanxi Xianfeng Biotechnology Co., Ltd). Rabbit polyclonal MACC1 (cat. no. ab106579; Abcam, Hong Kong, China;1:200) and rabbit monoclonal HK2 (cat. no. C64G5; Cell Signaling Technology, Danvers, MA, USA; 1:100) antibodies were used in immuno-histochemical analysis (IHC) using the streptavidin-peroxidase conjugated method. In brief, following antigen retrieval in a citrate buffer (Shaanxi Xianfeng Biotechnology Co., Ltd) using a microwave (350W; Midea Group Co., Ltd, Guangdong, China) for 15 min; the sections were then incubated with normal serum (Shaanxi Xianfeng Biotechnology Co., Ltd) at 37°C for 30 min and then with the primary antibody against MACC1 or HK2 at 4°C overnight. Sections were washed with PBS (Shaanxi Xianfeng Biotechnology Co., Ltd) and incubated with biotinated goat anti-rabbit monoclonal secondary antibodies (cat no. SP-9000-D; Zhongshan Goldenbridge Biotechnology Co., Ltd, Beijing, China) and avidin-biotin-peroxidase complex (Zhongshan Goldenbridge Biotechnology Co., Ltd) according to the manufacturer's instructions. The positive signal was visualized by incubating the sections with a diaminobenzidine solution (Shaanxi Xianfeng Biotechnology Co., Ltd) and counterstaining with hematoxylin (Shaanxi Xianfeng Biotechnology Co., Ltd). The sections were then observed under an inverted microscope (Nikon China Co., Ltd, Tokyo, Japan). The staining intensity was expressed as four grades: 0, none; 1, weak; 2, moderate; and 3, strong under 10 randomly selected independent high magnification (magnification, x400) fields. The percentages of positive carcinoma cells were expressed as the following grades: 0, <1%; 1, 10-25%; 2, 26-50%; 3, 51-75%; and 4, >75%. The total score was calculated by summatng the staining intensity and the percentage of positive tumor cells. Sections with a total score >2 were defined as exhibiting positive staining for the above two proteins.

Western blot analysis. Rabbit polyclonal MACC1 (cat. no. ab106579; Abcam; 1:1,000), rabbit monoclonal HK2 (1:1,000) and mouse monoclonal β-actin (cat. no. sc-47778, Santa Cruz Biotechnology, Inc., Santa Cruz, CA, USA; 1:1,000) antibodies were used for western blot analysis. Secondary horseradish peroxidase-conjugated goat anti-mouse or rabbit antibodies (Bio-Rad, Laboratories, Inc., Hercules, CA, USA) were used at a 1:5,000 dilution.

 Briefly, equal quantities of the protein samples were separated by denaturing gel electrophoresis (Bio-Rad Laboratories, Inc.). Following transfer onto a polyvinylidene difluoride membrane (Millipore, Billerica, MA, USA) blot membranes were incubated overnight with the primary antibodies (MACC1, HK2 and β-actin) respectively. Following washing 3 times in Tris-buffered saline with Tween 20 (Sino-American Biotechnology, He'nan, China), the sections were then incubated with the relevant goat anti-rabbit and goat anti-mouse immunoglobulin G monoclonal secondary antibodies (cat nos. sc-2004 and sc-2005; Santa Cruz Biotechnology, Inc.; 1:15,000) conjugated with horseradish peroxidase (HRP) and signals were visualized using the HyGLO HRP detection kit from Denville Scientific (Metuchen, NJ, USA).

Reverse transcription quantitative polymerase chain reaction (RT-qPCR). Total cellular RNA was extracted from the cultured cells using a Fastgen200 RNA isolation System (Fastgen, Shanghai, China). cDNA synthesis was achieved using the High Capacity cDNA Reverse Transcription kit (Applied Biosystems, Carlsbad, CA, USA). cDNA synthesis was achieved using the High Capacity cDNA Reverse Transcription kit (Applied Biosystems, Carlsbad, CA, USA).
RT-qPCR was performed using SYBR Green PCR master mix (Takara Bio, Inc., Dalian, China) using an IQ5 system (Bio-Rad Laboratories, Inc.). The primers to detect mRNA were as follows: MACC1, forward 5’-CTTGCGGAGGTCACCATAGC-3’ and reverse 5’-GATTTCCAACAACGGGCTCA-3’. All the samples were normalized to internal controls and fold-changes were calculated through relative quantification. Each measurement was performed in triplicate.

Metabolic assay of glycogen. Glycogen measurements were performed using a glycogen concentration kit (Biovision, Milpitas, CA, USA) according to the KOH-anthone method, described by Liu et al (22). Lactate quantifications in the media, following transfection or planting, were performed using a Lactate assay kit II (Biovision). Experiments were performed in triplicate.

Colony formation assay. A total of 100 HepG2-vector and HepG2-MACC1 cells were placed in a fresh six-well plate in triplicate and maintained in DMEM containing 10% FBS in a humidified 5% CO₂ incubator at 37°C for 2 weeks. The cell colonies were fixed with 20% methanol and stained with 0.1% coomassie brilliant blue R250 at room temperature for 15 min. The colonies were counted using a ELIspot Bioreader 5000 (Bio-Sys, Karben, Germany).

Statistical analysis. Differences between groups were compared using the χ² test, Fisher's exact test, the Mann-Whitney test and an analysis of variance. P<0.05 was considered to indicate a statistically significant difference. The SPSS 13.0 statistical package (SPSS, Inc., Chicago, IL, USA) was used for all calculations.

Results

MACC1 is overexpressed and accompanied by the expression of HK2 in HCC tissue. The IHC staining of the protein expression of MACC1 was positive in 59/80 (73.8%) of the
HCC tissues compared with 23/80 (28.8%) of the adjacent liver tissues, while the protein expression of HK2 was positive in 56/80 (70%) and 25/80 (31.3%; P<0.001), respectively. In addition, the IHC scores also demonstrated that the protein expression of MACC1 was significantly higher in the HCC tissues compared with the adjacent liver tissues (4.50±2.31, vs. 1.32±1.52; P<0.001; Fig. 1A), as was the protein expression of HK2 (3.95±2.36 vs. 1.72±1.55; P<0.001; Fig. 1B). The results of the IHC assay demonstrated that MACC1 protein was located predominantly in the nucleus and cytoplasm, while it was located in the cytoplasm in almost all the HK2-positive tumor tissues (Fig. 1).

In addition, western blot analysis revealed that MACC1 was positive in 20/24 (83.3%) of the HCC tissues compared with 11/24 (54.2%) in the adjacent liver tissues, while HK2 was positive in 21/24 (87.5%) and 13/24 (65.0%; P<0.05), respectively (Fig. 1K). The expression levels of the two proteins were significantly higher in the HCC tissues compared with the adjacent liver tissues.

Notably, the IHC data demonstrated that the expression of MACC1 was significantly associated with tumor staining for HK2 (odds ratio 3.89; 95% confidence interval (CI)=1.36-11.18; Spearman’s correlation=0.569; P=0.009), as shown in Fig. 1). This suggested that overexpression of the MACC1 protein in HCC tissues occurred with an increase in HK2 protein.

Correlation between the protein expression levels of MACC1 and HK2 and the clinical characteristics of HCC. Following analysis of the association between the expression levels of MACC1 and HK2 in HCC tissues and clinicopathological characteristics (Table I), it was revealed that positive MACC1 expression was significantly associated with large tumor size (r=0.332; P=0.004), a high Edmondson-Steiner classification (r=0.269; P=0.016) and an advanced tumor-mode-metastasis (TNM) stage (r=0.254; P=0.023). In addition, positive HK2 expression was significantly correlated with high Edmonson-Steiner classification (r=0.382; P=0.016) and advanced TNM stage (r=0.373; P=0.001), whereas no correlation was identified between other characteristics. These clinical data suggested that MACC1 and HK2 were closely associated with the process of HCC, and implied advanced HCC progression.
Figure 2. Rates of OS in patients with different expression levels of MACC1 and HK2. Solid lines indicate immunohistochemistry-positive samples while dotted lines indicate immunohistochemistry-negative samples. (A) OS was significantly lower for patients with MACC1-positive tumors compared with patients with MACC1-negative tumors (Log-Rank test P=0.032). (B) OS was significantly lower for patients with HK2-positive tumors compared with patients with HK2-negative tumors (Log-Rank test P=0.015). (C) Among patients with HK2-negative tumors, OS did not differ significantly on the basis of MACC1 expression (Log-Rank test P=0.798). (D) Among patients with MACC1-negative tumors, OS did not differ significantly on the basis of HK2 expression (Log-Rank test P=0.308). (E) Among patients with HK2-negative tumors, OS was significantly lower in patients whose tumors were also MACC1-positive (Log-Rank test P=0.039). (F) Among patients with MACC1-positive tumors, OS was significantly lower in patients whose tumors were also HK2-positive (Log-Rank test P=0.016). OS, overall survival; HK2, hexokinase-2; MACC1, metastasis-associated in colon cancer-1.

Figure 3. Different (A) MACC1 protein and (B) mRNA expression levels in different liver cancer cell lines. Values are expressed as the mean ± standard error of the mean. MACC1, metastasis-associated in colon cancer-1 gene; HK2, hexokinase-2.
Association between survival rates and the tumor expression of MACC1 and HK2. Follow-up information was obtained from the 80 HCC cases. The median survival rate of 80 patients was 30 months (range 0-60 months). As compared by a Kaplan-Meier survival curve, MACC1-positive expression was significantly associated with a lower overall survival (OS) rate, with the median survival rate of 29 months in the 59 HCC patients compared with 60 months in the 21 HCC patients with MACC1-negative expression (Log-rank P=0.032; hazard ratio (HR)=1.99; 95% CI=1.06-3.72), as shown in Fig. 2A. In addition, HK2-positive expression was also significantly associated with a lower OS rate, with a median survival rate of 26 months in the 56 HCC patients compared with 56 months in the 24 HCC patients with HK2-negative expression (Log-rank P=0.015; HR=2.11; 95% CI=1.55-3.84), as shown in Fig. 2B.

In addition, among the 56 HCC patients with HK2-positive expression, a lower OS rate was identified in HCC patients whose samples were also MACC1-positive compared with MACC1-negative tumor samples (Log-rank P=0.039; HR=2.31; 95% CI=1.04-5.14; Fig. 2C). However, among the 24 HCC patients with HK2-negative expression, no significant change in mortality rate was observed if the patients had MACC1-positive expression (Log-rank P=0.798; Fig. 2E). By contrast, among the 59 HCC patients with MACC1-positive expression, a significantly decreased survival rate was observed in the HCC patients whose samples were also HK2-positive compared with HK2-negative tumor samples (Log-rank P=0.016; HR=2.37; 95%CI=1.17-4.78; Fig. 2D). However, among the 21 HCC patients with MACC1-negative expression, no significant change in mortality rate was observed if the patients had HK2 positive expression (Log-rank P=0.308; Fig. 2F). These data demonstrated that upregulation of the protein expression levels of MACC1 and HK2 led to a poor prognosis in HCC.

Differential protein and mRNA expression levels of MACC1 in HCC cell lines. Subsequently, western blot analysis and RT-qPCR were performed in six HCC cell lines (HepG2, Hep3B, SMMC-7721, Bel-7402, Hep7 and MHCC-97H) and a non-transformed human liver cell line (LO2), each of which had different biological characteristics. Among these HCC cell lines, HepG2 expressed the lowest level of MACC1 protein and mRNA, while MHCC-97H expressed a relatively high level of MACC1 protein and mRNA (Fig. 3).

Knockdown of MACC1 in MHCC-97H cells suppresses cell glucose metabolism and reduces proliferation. To further investigate the function of MACC1 in glucose metabolism in cancer, the expression of MACC1 was silenced in MHCC-97H cells by transfection with MACC1 siRNA. As shown in Fig. 4A and B, the protein expression levels of MACC1 and HK2 were significantly decreased following transfection with MACC1 siRNA. The determination of the glycogen concentration of the culture medium revealed that the knockdown of MACC1 markedly suppressed the glucose catabolism of MHCC-97H cells (48 and 72 h after transfection; P<0.001, respectively; Fig. 4C). Simultaneously, decreased lactate production also confirmed the inhibition of glucose catabolism.
The proliferation of MHCC-97H cells was evaluated with or without MACC1 siRNA transfection using an MTT assay. The MTT activity of the MHCC-97H cells transfected with MACC1 siRNA was markedly decreased compared with the control cells (48 and 72 h after transfection; \( P<0.001 \), respectively), implying decreased proliferation rates (Fig. 4E). These data suggested that MACC1 promoted glucose metabolism and proliferation.

Overexpression of MACC1 in HepG2 cells promotes cell glucose metabolism and increases replication. To confirm the observed findings, the protein and mRNA expression of MACC1 in HepG2 cells was increased through stable transfection with a MACC1-expressing plasmid, and the protein expression of HK2 increased accordingly (Fig. 5A and B). Subsequently, it was identified that the glycogen consumption of the HepG2 cells stably transfected with the MACC1 expressing plasmid (HepG2 MACC1 cells) was significantly higher compared with that of HepG2 cells transfected with the vector plasmid (HepG2 vector cells) 48 and 72 h after planting (\( P<0.01 \); Fig. 5C), with a similar trend in lactate accumulation (72 h after planting; \( P<0.01 \); Fig. 5D). The proliferation of the transfected HepG2 was subsequently evaluated using MTT and colony formation assays. The proliferation rate of the HepG2 MACC1 cells was significantly increased compared with

Figure 5. Overexpression of MACC1 enhances glucose metabolism and promotes proliferation of HepG2 cells. (A and B) expression of MACC1 and HK2 in the HepG2 cells were significantly increased by overexpression of MACC1 in western blotting and reverse transcription-quantitative polymerase chain reaction. (C and D) Glucose metabolism of HepG2 cells was markedly activated by overexpression of MACC1 by Metabolic assay. (E and F) Proliferation of HepG2 cells was significantly promoted by overexpression of MACC1 in the MTT and colony formation assay (\(*P<0.05\) and \(**P<0.001\)). Values are expressed as the mean ± standard error of the mean. HK2, hexokinase-2; MACC1, metastasis-associated in colon cancer-1.
the HepG2 vector cells via the MTT assay 48 and 72 h after planting (P<0.01; Fig. 5E). Furthermore, the colony forming ability of the HepG2 MACC1 cells was significantly enhanced compared with the HepG2 vector cell, as expected (P<0.05; Fig. 5F). These results further clarified that the overexpression of MACC1 promoted proliferation, partly through enhanced glucose metabolism.

Discussion

The present study introduced a noteworthy finding, confirmed by a number of in vitro assays, that the expression of MACC1 was significantly upregulated in HCC tissues and was accompanied by the increased protein expression of HK2. Clinical data and survival curve analysis revealed that increased protein expression levels of MACC1 and HK2 indicated a poor prognosis in HCC. In addition, knockdown of MACC1 in the MHCC‑97H cells led to a reduced rate of proliferation via a reduction in glucose metabolism by the decreased protein expression of HK2. Furthermore, overexpression of MACC1 in the HepG2 cells induced the opposite result, providing confirmation. It was hypothesized that MACC1 leads to a poor prognosis in HCC, partly through promoting proliferation via enhanced glucose metabolism.

HCC is one of the most common types of cancer worldwide and has a poor prognosis. Tumor resection at an early stage remains the most effective treatment for HCC, however, the lack of early diagnosis has resulted in numerous patients with HCC being unable to undergo resection. In the present study, the role of MACC1 and HK2, from clinical data, and the prognostic of HCC, from immunohistochemical, immunoblotting and survival curve analysis, were investigated and the protein expression levels of MACC1 and HK2 were markedly upregulated in HCC tissue and associated with high Edmondson-Steiner classification, advanced TNM stage and a poor prognosis in patients with HCC. These data indicated the potential development of MACC1 and HK2 as clinical prognostic biomarkers in the future.

As an oncogene, MACC1 contributes to neoplastic growth, invasion and metastasis through the activation of HGF/MET signaling in several types of tumor (5,9). Previous studies have revealed that increased protein expression levels of MACC1 and HK2 are significantly associated with a poor prognosis in HCC patients (17,23,24). However, the mechanism by which MACC1 and HK2 lead to a poor prognosis remains to be elucidated. The PI3K/Akt signaling pathway, downstream of HGF/MET, is known as one of the basic elements in the development of several types of tumor, involved in tumor cell growth, differentiation and apoptosis (25,26), and previous studies have demonstrated that the PI3K/Akt signaling pathway is also involved in glucose metabolism in tumors, through increased HK2 protein expression and phosphorylation (19,27-29). Therefore, it was hypothesized that MACC1 induced the tumor growth via promoting tumor glucose metabolism and led to a poor prognosis in patients with HCC. In the present study, the correlation between the protein expression levels of MACC1 and HK2 was initially confirmed using immunohistochemical and western blot analysis in HCC tissue. Subsequently, it was identified that knockdown of MACC1 in MHCC‑97H cells decreased the protein expression of HK2, which also inhibited tumor glucose metabolism and reduced proliferation, and may improve prognosis. Subsequent overexpression investigations confirmed these findings. These data suggested that MACC1 induced tumor glucose metabolism by increasing the protein expression of HK2 and caused rapid proliferation, which may lead to poor survival rates in patients with HCC. Although MACC1 was found to enhance the expression of HK2 in the MHCC‑97H and HepG2 cells, whether MACC1 regulates the transcription of HK2 directly remains to be elucidated. The present study aimed to examine the MACC1‑binding site of the HK2 promoter by performing out an electrophoretic mobility shift assay, however no positive results were obtained, which indicated that MACC1 may upregulate the expression of HK2 in an indirect manner.

In conclusion, the present study demonstrated that aberrantly increased expression levels of MACC1 and HK2 in HCC tissues were associated with a high Edmondson-Steiner classification and advanced TNM stage, and led to a poor prognosis in HCC patients. In addition, MACC1 induced tumor glucose metabolism by upregulating HK2 indirectly and causing high levels of proliferation, which may be, in part the reason for the poor prognosis in HCC. MACC1 and HK2 may become potential clinical prognosis factors and targets for the treatment of HCC, however, further investigation is required to clarify the specific mechanism by which MACC1 promotes the progression of HCC.
